

## Solution Review: Problem Challenge 2

### We'll cover the following

- Structurally Unique Binary Search Trees (hard)
- Solution
- Code
  - Time complexity
  - Space complexity
- Memoized version

## Structurally Unique Binary Search Trees (hard) #

Given a number 'n', write a function to return all structurally unique Binary Search Trees (BST) that can store values 1 to 'n'?

Example 1:

```
Input: 2
Output: List containing root nodes of all structurally unique BSTs.
Explanation: Here are the 2 structurally unique BSTs storing all numbers from 1 to 2:
```

Example 2:

```
Input: 3
Output: List containing root nodes of all structurally unique BSTs.
Explanation: Here are the 5 structurally unique BSTs storing all numbers from 1 to 3:
```

## Solution #

This problem follows the [Subsets](#) pattern and is quite similar to [Evaluate Expression](#). Following a similar approach, we can iterate from 1 to 'n' and consider each number as the root of a tree. All smaller numbers will make up the left sub-tree and bigger numbers will make up the right sub-tree. We will make recursive calls for the left and right sub-trees

## Code #

Here is what our algorithm will look like:

Java Python3 C++ JS

```
1 import java.util.*;
2
3 class TreeNode {
4     int val;
5     TreeNode left;
6     TreeNode right;
7
8     TreeNode(int x) {
9         val = x;
```

```
10 }
11 };
12
13 class UniqueTrees {
14 public static List<TreeNode> findUniqueTrees(int n) {
15     if (n <= 0)
16         return new ArrayList<TreeNode>();
17     return findUniqueTreesRecursive(1, n);
18 }
19
20 public static List<TreeNode> findUniqueTreesRecursive(int start, int end) {
21     List<TreeNode> result = new ArrayList<>();
22     // base condition, return 'null' for an empty sub-tree
23     // consider n=1, in this case we will have start=end=1, this means we should have only one tree
24     // we will have two recursive calls, findUniqueTreesRecursive(1, 0) & (2, 1)
25     // both of these should return 'null' for the left and the right child
26     if (start > end) {
27         result.add(null);
28         return result;
29     }
30 }
```

### Time complexity #

The time complexity of this algorithm will be exponential and will be similar to [Balanced Parentheses](#). Estimated time complexity will be  $O(n * 2^n)$  but the actual time complexity ( $O(4^n / \sqrt{n})$ ) is bounded by the [Catalan number](#) and is beyond the scope of a coding interview. See more details [here](#).

### Space complexity #

The space complexity of this algorithm will be exponential too, estimated at  $O(2^n)$ , but the actual will be ( $O(4^n / \sqrt{n})$ ).

### Memoized version #

Since our algorithm has overlapping subproblems, can we use memoization to improve it? We could, but every time we return the result of a subproblem from the cache, we have to clone the result list because these trees will be used as the left or right child of a tree. This cloning is equivalent to reconstructing the trees, therefore, the overall time complexity of the memoized algorithm will also be the same.
